

IberiaNex Logistics — Consultant Brief

Prepared by: Ugo Ahukannah, SilverTrust · **Client:** IberiaNex Logistics S.A., Coslada, Madrid · **Date:** 26 August 2026
Basis: Discovery session with Gretel, Operations (fictional engagement scenario) · **Decision requested by:** end of next week

The problem

IberiaNex plans each morning on data it cannot trust, and runs each afternoon on a picture it cannot see. Routes are rebuilt by hand in Excel every day because the routing system is basic; on some days the plan is still being adjusted when the vans should already have left, and a late departure runs straight into Madrid peak traffic. After the hub gate there is no complete real-time view, so the fastest way to learn a delivery's status is to phone the driver — and customer service, who took the call, cannot answer from the screen. The cost is already visible: **12–14% failed first attempts** in the worst residential zones, each paid for twice through return-to-hub reprocessing, and **SLA penalties from two important B2C customers**. Two facts it relies on daily sit in no queryable system: the route knowledge that left with an experienced traffic manager, and the real range of the electric vans now running under Low Emission Zone rules. This is not a routing-algorithm problem — the planners know the roads. What they lack is clean addresses, an earlier start and a shared view after the gate.

The recommendation

1. **Clean addresses, honest delivery windows.** Normalise and geocode against 24 months of the company's own orders and proof-of-delivery records; score every stop for first-attempt risk; publish a realistic 1–2 hour window to the consignee. Low-confidence addresses go to a person, and the correction is kept.
2. **A morning plan that is already built.** An overnight route proposal from the closed order file, treating diesel and electric as different vehicles and applying LEZ access as a hard constraint, with local knowledge captured as reusable rules rather than one person's memory. The planner accepts, edits or rejects — nothing dispatches unreviewed.
3. **One picture of the day, without surveillance.** Five standardised delivery events from every driver, freelance included, so customer service answers at first line instead of escalating to traffic and then to the driver.

Out of scope, on purpose: no ERP replacement or migration; no continuous GPS tracking, driver scoring or automated disciplinary decisions; no system altering a customer commitment without a named person approving it; no change to night consolidation; no pilot activity during peak season.

Why it fits this client

It runs beside live operations rather than interrupting them — the stated constraint that morning dispatch and night consolidation cannot stop. It reads exports the team already produces, so the ageing ERP is never on the critical path and is never written to. It honours the boundary set in discovery — route overrides, customer exceptions, safety and workforce decisions stay with people, and event capture is minimal so drivers are not monitored. And it targets the stated 12-month goal: more reliable deliveries without adding vehicles or people as volume grows.

Measured on IberiaNex's own indicators: first-attempt success 86–88% → **93% or better**; plan locked 45 minutes before departure; **40% less planner time** building routes; zero SLA penalties in the pilot zone.

Next step

An **eight-week pilot in one Madrid metro zone — the worst residential zone, not the easiest**, so a result there can be trusted elsewhere. Weeks 1–2 baseline it as it runs today; weeks 3–4 run in shadow while planners work unchanged; weeks 5–7 go live with the planner keeping the override; week 8 decides on the measured result. **To start, three non-technical decisions:** name the zone; nominate one traffic planner as owner, two hours a week; approve read-only access to 24 months of orders, addresses and proof of delivery.
